BACKGROUND

- More than 5% of the world's population—over 430 million people—live with disabling hearing loss. This shows how important it is to have communication tools that are simple and accessible.
- Around 20% of people worldwide live with some degree of hearing loss, so communication accessibility affects a much larger group than we often realize.
- Sign language gives people a natural way to communicate, but when the person they are talking to does not understand it, even a simple conversation can become difficult and frustrating.
- Whether it is a classroom, hospital, workplace, or public service, users need a way to communicate quickly, comfortably, and independently using technology that is easy to access.

PROBLEM STATEMENT

- By 2050, more than 700 million people—around 1 in 10 people worldwide— are expected to have disabling hearing loss, making accessible communication solutions even more important.
- There is still a clear communication gap between people who use sign language and people who do not understand it, which can make everyday interactions challenging.
- Human interpreters and specialized hardware can help, but they may not always be available, affordable, or practical when communication is needed.
- Existing sign language translation systems can still struggle with accuracy, real-time performance, affordability, and ease of use, creating a need for a more convenient AI-powered solution.
